

84 Scenario Risk Model

Japan Property Investment

Based on 30 years of historical FX and property data, this report models 84 possible investment outcomes across 7 exchange rate scenarios, 4 property price trajectories, and 3 holding periods to provide a comprehensive risk assessment for Hong Kong investors.

Sample Property: Osaka Ten-no-Chaya Area

Investment: JPY 62,400,000 / HKD 3,200,000

Model: 7 FX x 4 Property Price x 3 Holding Periods

1. Understanding Our Model

When a Hong Kong investor purchases a Japanese property, the ultimate return depends on two fundamentally different categories of factors. Our model divides all input parameters into **Fixed Data** (already known today) and **Variable Data** (unknown, requiring scenario testing). By systematically testing all combinations, we generate 84 distinct investment scenarios that comprehensively cover the full range of possible return outcomes. Each scenario is measured by return rate (%) and absolute HKD gain/loss, helping investors understand exactly how their HKD 1.92M equity investment would perform under optimistic, average, and pessimistic conditions.

Fixed Data (Known Today)

Parameter	Value	Certainty
Property Purchase Price	JPY 62,400,000	Confirmed at purchase
Loan-to-Value (LTV)	40%	Set by lender
Mortgage Rate	3.0% (p.a.)	Fixed rate
Loan Term	15 years	Contractually fixed
Rental Yield	6.0% (gross yield)	Based on local rents
Annual Costs (Tax + Insurance)	0.3% of property value	No management fees

Variable Data (Unknown - Scenario Tested)

Parameter	Status	Scenario Range
Exit JPY/HKD Exchange Rate	Unknown	7 levels: 13.0 - 28.0
Exit Property Value	Unknown	4 annual rates: -3% to +3%
Holding Period	Flexible	3 options: 5, 7, 10 years

How the 84 scenarios work: We cross-combine 7 exit exchange rates (yen appreciating 33% to depreciating 44%), 4 property price annual change trajectories (-3% to +3%), and 3 holding periods (5, 7, 10 years) to produce 84 investment outcomes. Each outcome is measured by equity return rate (ROI%) and absolute HKD gain/loss.

Why no management fees: This analysis assumes the investor holds the property directly and self-manages it, so the only unavoidable costs are property taxes and building insurance (0.3% per year). Compared to fund-type investments, this significantly boosts net cash flow and makes returns more attractive.

2. Your Investment Parameters

The target property is located in the Tennoji-Chayamachi area of Osaka. Below are the fixed financial parameters used to construct the 84-scenario model. All values are based on current market conditions and loan terms. The investor purchases the property for HKD 3.20M (converted at rate 19.5 to JPY 62.40M), of which 40% comes from the loan and 60% is equity.

Property Purchase Price	JPY 62,400,000
Entry Exchange Rate	19.5 JPY/HKD
Property Value (HKD)	HKD 320.0M
Loan Amount (40% LTV)	JPY 2,496
Equity (Down Payment)	JPY 3,744 = HKD 192.00M
Mortgage Rate	3.0% (fixed p.a.)
Loan Term	15 years
Monthly Payment	JPY 172,369
Annual Mortgage Total	JPY 2.07M

Annual Cashflow Breakdown

Item	Annual Amount (JPY)	Notes
Gross Rental Income	JPY 3.74M	6.0% yield
Less: Property Tax + Insurance	- JPY 0.187M	0.3% of property value
Net Rental (before mortgage)	JPY 3.56M	
Less: Mortgage Payment	- JPY 2.07M	3.0%, 15-year term
Net Annual Cashflow	JPY 1.49M	Positive cashflow

Loan Balance at Exit

Holding Period	Loan Balance	Repaid
5 years	JPY 17.9M	JPY 7.1M (28%)
7 years	JPY 14.7M	JPY 10.3M (41%)
10 years	JPY 9.6M	JPY 15.4M (62%)

3. Market Variables: The Two Unknowns

3.1 Exchange Rate Scenarios (JPY/HKD)

The current JPY/HKD rate is approximately 19.5. Over the past 30 years, this rate has fluctuated between a low of 622 (1998, yen extremely strong) and a high of 1,181 (2024, yen extremely weak). Our 7 scenarios cover the full range from the yen appreciating 33% (rate falling to 13.0) to depreciating 44% (rate rising to 28.0). For HKD investors, a rising JPY/HKD rate means the yen is weakening, so converting yen assets back to HKD at exit yields more HKD — a positive factor.

Scenario	Exit Rate	FX Change	Impact on HKD Investor
Yen significantly stronger	13.0	+33.0%	Highly negative
Yen moderately stronger	15.0	+23.1%	Negative
Yen mildly stronger	17.0	+12.8%	Slightly negative
Unchanged (base case)	19.5	0.0%	Neutral
Yen mildly weaker	22.0	-12.8%	Slightly positive
Yen moderately weaker	25.0	-28.2%	Positive
Yen significantly weaker	28.0	-43.6%	Highly positive

3.2 Property Price Scenarios

Japanese property prices have experienced massive cyclical changes: the post-bubble decline (1990s-2000s), a long period of stagnation, and the recent urban renaissance (2012 to present). We test 4 annualized change rates, from -3%/year (similar to the 1995-2005 national average decline) to +3%/year (similar to the strong growth seen in Osaka/Tokyo metro areas from 2015-2025).

Annual Rate	5-Year Total	7-Year Total	10-Year Total	Historical Reference
-3%/yr	-14.0%	-19.3%	-26.3%	1995-2005 national decline
-1%/yr	-4.9%	-6.7%	-9.6%	2005-2015 stagnation
+1%/yr	+5.1%	+7.2%	+10.5%	Conservative urban recovery
+3%/yr	+15.9%	+23.0%	+34.4%	2015-2025 Osaka/Tokyo boom

4. 84 Scenario Results

Each cell below shows the return rate (%) and HKD gain/loss (in thousands) for your HKD 1.92M equity investment under the corresponding exchange rate and property price conditions. Green represents positive returns, yellow represents moderate positive returns, and red represents losses. Values shown as "k" represent thousands of HKD.

4.1 Holding Period: 5 Years

4.4 Visualization: 10-Year Return Heatmap

The heatmap clearly shows that the exchange rate (horizontal axis) is the single most dominant factor determining investment outcomes. Even when property prices decline, as long as the yen weakens at exit (rate shifts right), substantial positive returns can still be generated. The red zone (upper-left corner) only appears under the extreme combination of a significantly stronger yen and simultaneously declining property prices — a historically rare occurrence. For a 10-year holding period investor, nearly all 84 scenarios produce positive returns, demonstrating the effectiveness of a long-term holding strategy with positive cashflow.

5. Historical Evidence: 30-Year Summary

To validate the model, we analyzed all rolling 10-year windows between 1995 and 2025 (16 periods total), identifying the worst, average, and best scenarios that actually occurred in history. Using a same-period methodology — where both the exchange rate and property price changes come from the same 10-year window — we apply these real-world conditions to our investment model to show how your HKD 1.92M investment would have performed under actual historical conditions.

5.1 30-Year Cumulative Change

Indicator	1995 Level	2025 Level	30-Year Change
JPY/HKD Rate	733	1167	+59.3%
Residential Property Index (2015=100)	145.0	136.0	-6.2%

Over the past 30 years, the JPY/HKD rate rose from 733 to 1,167 (+59.3%), meaning the yen depreciated significantly against the HKD. For HKD investors, this long-term yen depreciation trend is a powerful tailwind: when you sell Japanese assets and convert yen back to HKD, each 100 yen buys more HKD than when you invested. Although the national property price index fell 6.2% cumulatively over 30 years, urban core areas (such as Osaka and Tokyo) significantly outperformed the national average, with core areas recording cumulative gains of 30-40% since 2012, underscoring the importance of location selection.

5.2 Historical 10-Year Scenarios: Visual Summary

The left chart shows the actual 10-year exchange rate and property price changes observed in history (worst, average, best). The right chart translates these changes into returns on your specific investment, presented as both percentage and HKD amount.

5.3 Your Investment: Three Historical Scenarios Compared (10-Year Hold)

The table below applies historically observed 10-year exchange rate and property price changes (using same-period methodology) to your HKD 1.92M equity investment, showing what you would have actually gained or lost under those historical conditions.

	Worst Case	Average Case	Best Case
Historical Period (FX)	1995-2005	Average of 16 periods	2002-2012
Historical Period (Property)	1995-2005	Average of 16 periods	2002-2012
10-Year FX Change	+17.2%	-5.1%	-36.3%
10-Year Property Price Change	-40.0%	-3.9%	-10.8%
Exit Property Value	JPY 37.4M	JPY 59.9M	JPY 55.7M
Exit Loan Balance	JPY 9.6M	JPY 9.6M	JPY 9.6M
Net Exit Proceeds (JPY)	JPY 27.8M	JPY 50.3M	JPY 46.1M
Cumulative Rental Income (10yr)	JPY 14.9M	JPY 14.9M	JPY 14.9M
Total Return (HKD)	HKD 1,870k	HKD 3,593k	HKD 4,906k
Equity Return (ROI)	-2.6%	+87.1%	+155.5%
HKD Gain/Loss	HKD -50k	HKD +1,673k	HKD +2,986k

Key Insight: Even in the worst 10-year period in history (yen depreciating 64.7% combined with property prices falling 40.0%), the loss was only -2.6% (HKD -50k), substantially buffered by JPY 14.9M in cumulative positive cashflow income. The average scenario returned +87.1% (HKD +1673k), nearly doubling your equity. The best scenario achieved +155.5% (HKD +2986k), representing approximately a 2.6x growth on the original investment. These three historical scenarios clearly demonstrate that the positive cashflow strategy plays a critical risk-buffering role in long-term holdings.

6. Risk Scorecard

Below is a comprehensive risk assessment of this investment across five dimensions. Each risk factor is analyzed based on historical data and current market conditions, with ratings informed by the 84-scenario model results.

Risk Category	Rating	Assessment
Exchange Rate Risk	Medium	30-year trend: yen depreciated 59% against HKD (favorable). Short-term: BOJ rate at 0.75% may push yen higher. Medium-term fiscal pressures favor HKD investors. 7 exit rates tested.
Property Value Risk	Low-Med	Osaka metro has seen strong recovery since 2012. Foreign investment at record highs. 2025 Expo infrastructure continues to support growth. National decline data masks strong core urban performance.
Liquidity Risk	Low	Osaka core area selling period of 2-4 months. No capital controls. FEFTA (April 2026) only adds administrative procedures.
Policy Risk	Medium	FEFTA filing required from April 2026. BOJ may continue raising rates. No property tax reform proposals at present.
Rental Income Risk	Low	Osaka vacancy rate below 5%. 6% yield assumption is conservative. Even with 20% rent decline, positive cashflow is maintained after mortgage deduction.

Statistical Summary (All 84 Scenarios)

Statistic	Return Rate (%)	HKD Gain/Loss
Minimum (worst)	-19.7%	HKD -378k
25th Percentile	+27.6%	HKD +529k
Median	+60.2%	HKD +1,156k
75th Percentile	+98.2%	HKD +1,886k
Maximum (best)	+257.2%	HKD +4,938k
Positive Return Scenarios	78/84 (93%)	
Negative Return Scenarios	6/84 (7%)	

Conclusion

93% of the 84 scenarios produce positive returns. The historical average scenario return is +87.1%. The worst historical 10-year return was -2.6% (effectively controlled by positive cashflow). The primary risk lies in potential short-term yen strength driven by BOJ monetary tightening; however, for investors with a 7-10 year holding period, sustained rental income and the long-term yen depreciation

trend will provide strong support for the investment. Overall, at current exchange rate levels and interest rate conditions, Japanese property investment offers relatively favorable risk-return characteristics for Hong Kong investors.
